ABSTRACT

In this paper we study the implication and the finite implication problems for data dependencies. When all dependencies are total the problems are equivalent and solvable but are NP-hard, i.e., probably computationally intractable. For non-total dependencies the implication problem is unsolvable, and the finite implication problem is not even partially solvable. Thus, there can be no formal system for finite implication. The meta decision problems of deciding for a given class of dependencies whether the implication problem is solvable or whether implication is equivalent to finite implication are also unsolvable.

1. INTRODUCTION

One of the important issues in the design of relational database schemas is the specification of the constraints that the data must satisfy to model correctly the part of the world under consideration. These constraints determine which databases are considered meaningful.

Of particular interest are the constraints called data dependencies. The first class of dependencies to be studied was the class of functional dependencies [Codd], which was followed by the class of multivalued dependencies [Fag1,2an]. Recently, a number of generalizations of these dependencies have appeared; e.g., join dependencies [ABU,Kiss], general dependencies [JF], and template dependencies [SU]. All these classes are subclasses of the class of tuple and equality generating dependencies of [BV2,Fag2,YP]. Intuitively, the meaning of a dependency is that if some tuples, fulfilling certain conditions, exist in the database, then either some other tuples must also exist therein, or some values in the given tuples must be equal.

A utilization of the above dependencies in the design of a relational database requires algorithms for determining whether a set of dependencies is redundant.

(Berl) and whether two sets of dependencies are equivalent ([EMSU,Berl]). Both problems reduce to the implication problem, i.e., the problem of deciding whether a given set of dependencies logically implies another dependency. The finite implication problem is the problem of implication when only finite relations are taken into account.

The formalism is that of first order logic. We do not show how the various dependencies mentioned above can be written in this formalism, and the reader interested in that aspect is referred to [BV1, Nic]. In fact, we mostly refrain from using "relational" terminology, and except for a few remarks this paper is essentially concerned with a fragment of first order logic, which is relevant to database theory.

This paper is an abridged version of [BV1].

2. DEPENDENCIES

We use the language $L(n)$ of first order logic with equality with no function symbols and one $n$-ary predicate symbol. Indexed $x$'s are used for existentially quantified variable symbols, and indexed $y$'s are used for universally quantified variable symbols. Indexed $v$'s are syntactical variables ranging over variable symbols. An atomic formula $R(v_1,\ldots,v_n)$ is called a predicate formula and an atomic formula $v_i = v_j$ is called an equality formula. A dependency is a sentence

$$
\forall v_1 \ldots \forall v_k \exists x_1 \ldots \exists x_1 (A_1 \land \ldots \land A_p \rightarrow B_1 \land \ldots \land B_q),
$$

where:

(a) $k, p, q \geq 1, i \geq 0$.

(b) the $A$'s and the $B$'s are atomic formulas.

(c) at least one $A_i$ is a predicate formula.

(d) the set of variables occurring in the $A$'s is the same as the set of variables occurring in the predicated $A$'s, and is exactly $(v_1, \ldots, v_k)$.

(e) the set of variables occurring in the $B$'s contains $(x_1, \ldots, x_i)$.

Restrictions (c) and (d) ensure that the sentence refers only to the information contained within the database.

Suppose now that some $A_i$ is $v_i = v_j$. Obviously, we can identify $v_i$ and $v_j$ wherever they occur in the dependency, and eliminate $A_i$ to get an equivalent dependency. Thus, we can assume

(f) all the $A$'s are predicate formulas.

Suppose now that some $B_i$ is $x_i = v_j$. Again, we can identify $x_i$ and $v_j$ and eliminate $B_i$ to get an equivalent dependency. Thus, we can assume:
(4) All equality formulas are of the form $v_i = v_j$.

Finally, recalling that $\forall y(A \land B \land C)$ is equivalent to $\forall y(A \land B) \land \forall y(A \land C)$, if $y$ is free in $A, B$, and $C$, we assume:

(5) Either all the $B$'s are predicate formulas or $q=1$ and $B_1$ is an equality formula.

Intuitively, the meaning of a dependency is that if some tuples, fulfilling certain conditions, exist in the database, then either some other tuples must also exist therein, or some values in the given tuples must be equal.

We now distinguish between several subclasses of dependencies. This is summarized in the following table:

<table>
<thead>
<tr>
<th>Case</th>
<th>Name</th>
<th>Abbreviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>All $B$'s are predicate formulas</td>
<td>Tuple generating</td>
<td>tgd</td>
</tr>
<tr>
<td>$q=1$ and $B_1$ is an equality formula</td>
<td>Equality generating</td>
<td>egd</td>
</tr>
<tr>
<td>$i=0$ (no existential quantifier)</td>
<td>Total</td>
<td>td</td>
</tr>
<tr>
<td>$q=1$</td>
<td>Many to one</td>
<td>mod</td>
</tr>
<tr>
<td>$p=2$ and $q=1$</td>
<td>Two to one</td>
<td>tod</td>
</tr>
<tr>
<td>Many sorted (see definition)</td>
<td>Many sorted</td>
<td>msd</td>
</tr>
</tbody>
</table>

A dependency is many sorted if no variable occurs in two different argument positions of the predicate symbol, and only variables which occur in the same argument position of the predicate symbol can be the arguments of an equality formula. Almost all dependencies dealt with in the literature are msd's. For example, for msd's:

1. An egd with $p=2$ is a functional dependency [Codd].
2. A tgd with $q=1$ is a template dependency [SU].

Remark. One may ask whether our syntactic definitions for dependencies can be replaced by semantic definitions. To a certain degree this can be done [CLM]. However, semantic definitions can characterize only up to logical equivalence, and the set of first order sentences equivalent to some dependency is not recursive. $\Rightarrow$

The dependencies of $L(n)$ are called $n$-ary dependencies. In studying decision problems for $L(n)$, $n$ may be either a parameter of the problem or some fixed value. The class of all dependencies is denoted $\text{Dep}$. In the sequel we use $D$ to denote a finite set of dependencies and $d, d'$ to denote single dependencies. In writing down dependencies we usually omit universal quantifiers.
3. IMPLICATION PROBLEMS

Let $U = \langle A, R \rangle$ be a structure for $L(n)$. $U$ is finite if $A$ is finite (and consequently, $R$ is finite). $U$ is semifinite if $R$ is finite ($A$ can be infinite). $U$ is infinite if $R$ is infinite (and obviously, $A$ is infinite). $U$ is empty if $R$ is empty, and is trivial if it is empty or if $|A| = 1$. (Note that $A$ is always assumed to be nonempty).

A set of dependencies $D$ implies a dependency $d$, denoted $D \models d$, if $d$ holds in all models of $D$. $D$ semifinitely implies $d$, denoted $D \models_{sf} d$, if $d$ holds in all semifinite models of $D$.

$D$ finitely implies $d$, denoted $D \models_f d$, if $d$ holds in all finite models of $D$. Clearly, real-life databases are finite, but the domain of values might be conceptually infinite. However, for dependencies $\models_{sf}$ and $\models_f$ are equivalent.

Lemma 1. $D \models_{sf} d$ iff $D \models_f d$. $\iff$

By Lemma 1 it suffices to deal with $\models$ and $\models_f$. Our decision problems are:

(a) The implication problem - for a given $D$ and $d$, decide whether $D \models d$.

(b) The finite implication problem - for a given $D$ and $d$, decide whether $D \models_f d$.

The (finite) implication problem of type $(C_1; C_2)$, where $C_1$ and $C_2$ are classes of dependencies is the (finite) implication problem for $D \subseteq C_1$ and $d \in C_2$. That is, for such $D,d$ decide whether $D \models_{f}(d)$.

As is well-known, both the implication and the finite implication problems are unsolvable for arbitrary first order sentences. Note that $D \models d$ entails $D \models_f d$, but not vice versa, hence, the implication and the finite implication problems are independent. In fact, their equivalence entails their solvability.

Lemma 2. The following sets are recursively enumerable:

(a) $\langle D,d \rangle \mid D \models d$.

(b) $\langle D,d \rangle \mid D \models_f d$. $\iff$

Corollary. If for classes of dependencies $C_1$ and $C_2$ we have that for $D \subseteq C_1$ and $d \in C_2$, $D \models d$ iff $D \models_f d$, then the implication problem of type $(C_1; C_2)$ is equivalent to the finite implication problem and is solvable. $\iff$

Let us now consider the case where $D$ is the empty set. A dependency $d$ is trivial if it holds in all structures, denoted $\models d$, and is finitely trivial
if it holds in all finite structures, denoted \( \vdash d \). Thus, as special cases of the (finite) implication problem, we get:

(a) The **triviality problem** - for a given \( d \), decide whether \( d \) is trivial.

(b) The **finite triviality problem** - for a given \( d \), decide whether \( d \) is finitely trivial.

4. **Some Solvable Cases**

If we restrict \( D \) to be a set of \( t\delta \)'s, then the (finite) implication problem is equivalent to the (finite) validity problem for \( \Sigma^* \Sigma^* \) sentences (Schonfinkel-Bernays class), whose solvability follows from Lemma 2 [BS].

**Theorem 1.** The implication problem of type \( (t\delta \;'s \; ; \; \text{Dep}) \) is equivalent to the finite implication problem, and is solvable. \( \leftrightarrow \)

As a special case we get the solvability of the (finite) triviality problem.

**Theorem 2.** A dependency \( d \) is trivial iff it is finitely trivial iff

(a) \( d \) is a \( t\gamma \)d and \( B_1 \) is \( y_1 = y_1 \), or

(b) \( d \) is a \( t\delta \)d and for some substitution sequence \( 1 \leq i_1, \ldots, i_k \leq k \),
\( \{B_{i_1}, \ldots, B_{i_k}\} \) \( \{y_1/y_1, \ldots, x_1/y_1\} \) \( \subseteq \{A_1, \ldots, A_p\} \). \( \leftrightarrow \)

A decision procedure for the implication problem of type \( (t\delta \;'s \; ; \; \text{Dep}) \) is described in [BV2]. In some more restricted cases there is an efficient decision procedure [BE,Beer,BV2,MSY,Va], but this is not the case in general. We provide now some upper and lower time bounds.

The following upper bound follows from the complexity analysis of the above mentioned decision procedure [BV2].

**Theorem 3.** Let \( D \) be a set of \( n \)-ary \( t\delta \)'s with \( u \) universal quantifiers, and let \( d \) be an \( n \)-ary dependency with \( p \) universal quantifiers and \( e \) existential quantifiers. Let \( s \) be the number of symbols in \( D \) and \( d \). The implication problem for \( D \) and \( d \) can be solved in time \( O(n \cdot 2^{2n+u+e}) \). \( \leftrightarrow \)

The following theorems imply that, except in some restricted cases, there is probably no efficient decision procedure for the implication problem for this solvable case.

**Theorem 4.** The triviality problem for \( t\delta \)'s is \( NP \)-complete, even for \( mad \)'s and binary dependencies.

**Proof:** In \( NP \): Nondeterministically choose a substitution sequence and check for the condition of the Theorem 2.

Hard for \( NP \):
(a) msd's: reduction from EXACT COVER [Ka].

(b) binary dependencies: reduction from CLIQUE [Ka].

Theorem 5. The set \(<d, d'> \mid d, d' \text{ are total msd's and } d \not\subseteq d'\) is NP-hard even for msd's and binary dependencies.

Proof: We use the following NP-complete problems for reduction:

(a) Msd's: reduction from EXACT COVER [Ka].

(b) Binary dependencies: reduction from CLIQUE [Ka].

Additional results on the complexity of testing implication of msd's can be found in [BV3].

In some cases solvability follows from the fact that the answer to the decision problem is trivially negative:

Lemma 3. Let \(D\) be a set of tgd's, and let \(d\) be an egd, then \(D \models d\) if and only if \(D \models \bar{d}\) if and only if \(d\) is trivial. 

For several other solvable cases see [BV2].

When dealing with implication of tgd's, we can very easily eliminate egd's from consideration. Let \(d\) be the egd \(\forall y_1 \ldots \forall y_k (A_1 \land \ldots \land A_p \land y_1 = y_2)\). Let \(A\) denote the predicate formula \(R(y_{k+1} \ldots y_{k+m})\), and denote by \(A(m/y_1)\), for \(1 \leq m \leq n\), the result of substituting \(y_1\) for \(y_{k+m}\) in \(A\). We associate with \(d\) the following set of tgd's: \(D_1\) is \(\left\{ \forall y_1 \ldots \forall y_{k+m} (A_1 \land \ldots \land A_p \land A(m/y_1) + A(m/y_2)) \mid 1 \leq m \leq n \right\}\). \(D_2\) is defined similarly, with \(g\) and \(h\) interchanged, and \(D_4\) is taken to be the union of \(D_1\) and \(D_2\). Let \(D\) be a set of dependencies, we denote by \(D^*\) the result of replacing each egd \(d\) in the set \(D\) by \(D_4\).

Lemma 4. Let \(D\) be a set of dependencies and \(d\) a tgd, then \(D \models d\) iff \(D^* \models d\) and \(D \models \bar{d}\) iff \(D^* \models \bar{d}\).

It is well known that equality can be eliminated from first-order logic by adding the equality axioms: reflexivity, symmetry, transitivity and substitutivity. This can also be applied to dependencies. Actually, we can prove an even stronger result:

Theorem 6. Let \(D\) be a set of dependencies, and let \(d\) be a dependency. We can effectively construct a set of tuple generating tgd's \(D'\) and a tuple generating tgd \(d'\), such that \(D \models d\) if and only if \(D' \models d'\), and \(D \models \bar{d}\) if and only if \(D' \models \bar{d}'\).
5. UNSOLVABILITY RESULTS

The main result of this section is:

Theorem 7. The implication and the finite implication problems are unsolvable. ☐

Insolvability is shown by encoding appropriate unsolvable problems of
equational logic in terms of dependencies.

Let \( L_{eq} \) be the language of first order logic with equality, with function
symbols but no individual constants or predicate symbols. An equation is a
sentence \( \forall y_1 \ldots \forall y_k (s = t) \), where \( s \) and \( t \) are terms of \( L_{eq} \). A conditional
equation is a sentence \( \forall y_1 \ldots \forall y_k (s_1 = t_1 \land \ldots \land s_{m-1} = t_{m-1} \land s_m = t_m) \), \( m > 1 \),
where \( s_1, t_1, \ldots, s_m, t_m \) are terms of \( L_{eq} \). Equational logic is a fragment of
first order logic, in which equations and conditional equations are the only
admitted sentences.

Let \( L_2 \) be \( L_{eq} \) with one binary function symbol \( g \). A conditional
equation of \( L_2 \) is simple if it is of the form \( \forall y_1 \ldots \forall y_k (e(1) \land \ldots \land e(m) \Rightarrow e(m)) \),
where \( e(i) = g(v_1, v_2) = v_3 \) for \( 1 \leq i \leq m \), and \( e(m) \) is
\( v_k = v_1 \), \( 1 \leq k, 1 < m \), \( 1 \leq p, q \leq 3 \).

Lemma 5. For every (conditional) equation of \( L_2 \) we can effectively construct an
equivalent simple conditional equation. ☐

A structure \( U = \langle A, f_1, f_2, \ldots \rangle \) for \( L_{eq} \) is finite if \( A \) is finite, and
is trivial if \( |A| = 1 \). Clearly, every (conditional) equation has a trivial model.
Non-trivial consistency is, however, unsolvable.

Theorem 8. (McKe) The following two problems are unsolvable for \( L_2 \):
(a) to decide if an equation has a non-trivial model.
(b) to decide if an equation has a non-trivial finite model. ☐

Corollary. The above problems are unsolvable even for simple conditional
equations. ☐

Equations can be coded by dependencies by replacing functions by their
representing relations. Let \( U = \langle A, g \rangle \) be a structure for \( L_2 \), i.e., \( U \) is a
groupoid. The representing relation for \( U \) is a ternary relation
\[ G = \{<x, y, z> | z = g(x, y) \} \] .

G satisfies the following condition:
(*) For all \( x, y \), each belonging to some triple in \( G \), there exists a
unique \( z \) such that \( <x, y, z> \in G \).

Conversely, any non-empty ternary relation \( G \) on a set \( B \) satisfying (*) defines
a groupoid \( U = \langle A, g \rangle \), where \( A = \{x \mid <x, y, z> \in G \} \subseteq B \), and \( g(x, y) = z \),
where \( z \) is the unique element such that \( <x, y, z> \in G \).
Condition (*) is expressed by the following dependencies:

G1: \( 2x(G(y_1, y_2, y_3) \rightarrow G(y_2, y_3, x)) \)

G2: \( 3x(G(y_1, y_2, y_3) \land G(y_4, y_5, y_6) \rightarrow G(y_5, y_1, x)) \)

G3: \( G(y_1, y_2, y_3) \land G(y_4, y_2, y_4) \rightarrow y_3 = y_4 \)

Let Eq: \( \forall y_1 \ldots \forall y_k \in (e(1) \land \ldots \land e(m)) \) be a simple conditional equation. To express it in terms of the representing relation we replace the equality formula \( e(i) \) by the predicate formula \( E(i) : G(v_1^i, v_2^i, v_3^i) \) to get the representing dependency \( d_{eq}: \forall y_1 \ldots \forall y_k \in E(1) \land \ldots \land E(m) \rightarrow e(m) \).

Lemma 6. Let \( U = <A, g> \) be a non-trivial (finite) groupoid satisfying a simple conditional equation \( Eq \), then its representing relation \( G \) satisfies \( G, G_2, G_3, d_{eq} \). Conversely, if \( G \) is a non-trivial (finite) ternary relation satisfying \( G, G_2, G_3, d_{eq} \), then it defines a non-trivial (finite) groupoid satisfying Eq. \(<>\)

As an immediate consequence we get:

Theorem 9. The following two problems are unsolvable even for ternary mod's:

(a) to decide if a set of dependencies \( D \) has a non-trivial model.

(b) to decide if a set of dependencies \( D \) has a non-trivial finite model. \(<>\)

This result will serve as a springboard for proving the unsolvability of the implication and the finite implication problems. However, it does have a significance by itself, since if a database is described by a set of dependencies which have no (finite) non-trivial model, then this set is probably semantically meaningless.

Let \( Ga \) be \( G \), and let \( Gb \) be \( Ga^* \) (i.e., \( Gb \) is the result of replacing \( G3 \) by tgd's as described in Section 4). We define two dependencies:

T1: \( G(y_1, y_2, y_3) \rightarrow y_1 = y_2 \),

T2: \( G(y_1, y_2, y_3) \land G(y_1, y_4, y_5) \rightarrow G(y_1, y_2, y_4) \).

Theorem 10. The following sets of ternary tuple generating mod's are not recursive:

(a) \( \{ d \mid Ga \cup \{ d \} = T1 \} \),

(b) \( \{ d \mid Ga \cup \{ d \} = T2 \} \),

(c) \( \{ d \mid Gb \cup \{ d \} = T1 \} \),

(d) \( \{ d \mid Gb \cup \{ d \} = T2 \} \).

Proof. A groupoid is trivial iff it satisfies the equation \( \forall x \forall y (x = y) \) iff it satisfies the equation \( \forall x \forall y \forall z (g(x, y) = z) \). Since \( T1 \) and \( T2 \) represent these equations, the claim follows by Theorem 8 and Lemma 6. \(<>\)
The meaning of the above theorem is that the set of dependencies implying a specific dependency is not recursive. We are going now to construct a set of dependencies Gc, such that the set of dependencies implied by Gc is not recursive.

A group is a groupoid satisfying the following axioms [TMR]:

H1: g(x, g(y, z)) = g(g(x, y), z)
H2: ∃z(x = g(y, z))
H3: ∃z(x = g(z, y)).

These axioms are expressed by the following dependencies:

G4: G(y2, y3, y4) ∨ G(y1, y4, y5) ∨ G(y1, y2, y6) → G(y6, y3, y5),
G5: ∃z(G(y1, y2, y3) ∨ G(y2, x, y1)),
G6: ∃z(G(y1, y2, y3) ∨ G(x, y2, y1)).

The following theorem is the well-known unsolvability result for the word problem for groups (e.g. [Bo]).

Theorem 11. The set of conditional equations which holds in all groups in not recursive. \( \Leftarrow \)

Let Gc be \( \{G1, \ldots, G6\} \). Using Lemma 5 we get:

Theorem 12. The following set of ternary egd's is not recursive:
\( \{d \mid Gc \vdash d\}. \) \( \Leftarrow \)

6. MORE UNSOLVABILITY RESULTS

Actually, we have proved in the previous section a result which is stronger than Theorem 7.

Theorem 13. The (finite) implication problem for ternary tuple generating mod's is unsolvable. \( \Leftarrow \)

By using various reduction technique, we can also have:

Theorem 14. The (finite) implication problem for binary tgd's and for 5-ary tuple generating mod's is unsolvable. \( \Leftarrow \)

Remark. When constants are allowed to appear in dependencies (two constants suffice), the (finite) implication problem is unsolvable even for 4-ary many-sorted tuple generating mod's. \( \Leftarrow \)

For some sets of dependencies \( D_1, D_2 \), the set
\[ \text{IMPL}(D_1, D_2) = \{ d \mid d \in D_2 \text{ and } D_1 \vdash d \} \]

may be recursive. The meta implication problem is to decide, for given recursive sets of dependencies \( D_1, D_2 \), whether \( \text{IMPL}(D_1, D_2) \) is recursive.

**Theorem 15.** The meta implication problem is unsolvable.

**Proof.** The claim follows from the unsolvability of the meta word problem for groups [Raj].

Combining our unsolvability results with Lemma 2 we get:

**Theorem 16.** The following sets are not recursively enumerable:

- (a) \( \{<D,d> \mid D \vdash d \} \)
- (b) \( \{<D,d> \mid D \nvdash d \} \).

From part (a) of the theorem it follows that there is no proof procedure for finite implication of dependencies, and obviously no sound and complete formal system for finite implication can be found. In contrast, a proof procedure and a formal system for implication does exist [BV2, BV4, VP].

By the corollary of Lemma 2, \( \vdash \) and \( \nvdash \) are not equivalent for dependencies in general, and by Theorem 1 they are equivalent for some classes of dependencies. The implication equivalence problem is to decide, for given recursive sets of dependencies \( D_1, D_2 \), whether for all \( d \in D_2 \), \( D_1 \vdash d \) iff \( D_1 \nvdash d \).

**Theorem 17.** The implication equivalence problem is unsolvable.

**Proof:** The claim follows from the unsolvability of the residual finiteness problem for groups. [Raj].

We conclude by showing that \( \vdash \) and \( \nvdash \) are not equivalent even for binary mod's, though the solvability issue for this class is open. We use \( d_1, d_2, d_3, d_4 \) and \( d_5 \):

- \( d_1 \): \( \exists x (R(x,y) \land R(x,x)) \)
- \( d_2 \): \( R(y_1, y_2) \land R(y_2, y_3) \land R(y_1, y_3) \)
- \( d_3 \): \( R(y_1, y_1) \land R(y_2, y_2) \land R(y_3, y_3) \)
- \( d_4 \): \( \exists x (R(y_1, y_2) \land R(x, x)) \)
- \( d_5 \): \( R(y_1, y_2) \land R(y_2, y_1) \).

**Lemma 10.**

- (a) \( \{d_1, d_2\} \nvdash d_4 \) but \( \{d_1, d_2\} \vdash d_3 \)
- (b) \( \{d_1, d_2, d_3\} \nvdash d_5 \) but \( \{d_1, d_2, d_3\} \nvdash d_5 \).
7. CONCLUDING REMARKS

The originators of dependency theory intended to develop a tool for automated database design. Our lower bounds for (finite) implication indicate that in its present state the theory is far from being such a tool. Thus, the theory has not yet passed its 'true test' which is 'demonstrating its effectiveness in solving day to day database design problems' [BBG].

It should be noted however, that while unsolvability holds for fairly restricted classes of dependencies, we could not extend it for many-sorted mod's, and, more specifically, to embedded multivalued dependencies ([Fag1]) and embedded join dependencies ([NMS]). It is known that the (finite) implication problem for embedded multivalued and join dependencies of any fixed arity is solvable. It is also known ([Y]) that unsolvability for the class of many-sorted mod's entails unsolvability for a class which is slightly more general than the class of embedded join dependencies.

The implication problem is a "local" decision problem. As said in the introduction, our motivation for studying it was the search for algorithms to solve "global" decision problems: the equivalence problem and the redundancy problem. Since \(D \models d\iff D \cup \{d: \models d\} \models D\), unsolvability of the implication problem entails unsolvability of the equivalence problem. This is not the case for the redundancy problem. That and other "global" decision problems will be dealt with in a future paper.

Acknowledgements.
